The Unemotional Revolution:  
A Critique of Van Fraassen's Empiricist Picture of Scientific Revolution

In *The Empirical Stance*, Bas C. Van Fraassen presents two lectures on the topic of scientific revolution.<sup>1</sup> Arguing from the empiricist perspective, he puts forth a theory of scientific revolution using experience as the sole epistemic tool. According to Van Fraassen, our information about the world derives from experience, and we use our values and theoretical beliefs about the world to interpret our experiences. From this framework, he concludes that scientific revolution consists of a rational process of suspending some elements of our theoretical beliefs and replacing them with new theories. Furthermore, Van Fraassen argues that part of this revolutionary process requires an emotional leap akin to the transition felt during a sorrowful collapse or an angry tirade. In Van Fraassen's scientific revolution, we suffer a long buildup of evidence against the accepted theory, and when we can no longer hold our current theoretical beliefs, we throw them off violently and replace them with a new paradigm. In the same way that anger can bring us into a strange new mindset, the revolutionary process brings us to entertain new scientific theories. Due to our ability to suspend parts of our belief system without abandoning it in its entirety, Van Fraassen contends that this process is rational.

In this paper, I will argue that Van Fraassen's emotional mechanism for scientific revolution is wrongheaded in several ways. Firstly, he attempts to develop a rational model of scientific revolution with many clearly irrational elements. For example, his comparison of the revolutionary process to emotional leaps undermines his later claims about the rationality of

---

<sup>1</sup> "Lecture 3: Scientific Revolution/Conversion as a Philosophical Problem" and "Lecture 4: Experience (Epistemic) Life Without Foundations."

belief suspension. Furthermore, Van Fraassen sees scientific revolution as a largely individualistic process giving little attention to the scientific community during revolution. In particular, he fails to devote any attention to the reluctance of the older generation to give up old theories in the face of new ones presented by the younger generation. Combining Van Fraassen's analysis with the work of Larry Laudan and Ernan McMullin, I will present a view of scientific revolutionary that is less emotional, more gradual, and more community-centered than the one discussed by Van Fraassen.

To begin this discussion of scientific revolution, it is important to first address the idea of science as a rational practice. Perhaps the most important aspect of scientific revolution is that it leads us to question the view of science as fully rational. Regardless of the specific nature of scientific revolution, some such revolutions involve a drastic change in the methodology, epistemology, and values of the scientific community. Certain revolutions, such as the quantum mechanical revolution that I will discuss later, entail a change in the very conception of what scientists hold as a good theory. Since rationality in science depends heavily on the process of determining good theories, revolution would seem to undermine the very foundations of rationality in science. Since scientific revolution seems to act outside the framework of scientific rationality, it could be an irrational or non-rational process.

In both lectures, Van Fraassen examines the above problem extensively while outlining his theory of scientific revolution. He claims that if scientific revolution is found to be irrational, we will "find ourselves ruefully admitting that we came to our present fortunes by luckily vindicated lapses of reason or leaps of faith, perhaps taken only in sheer desperation" (111). This is the danger of seeing scientific revolution as irrational: it reduces scientific progress to

dumb luck. Van Fraassen contends that we do not see science in that way, and that a different mechanism is at work during scientific revolution.

Van Fraassen sees the problem of scientific revolution as one of a seemingly one-sided rationality. He claims: “a change in view is properly called radical or revolutionary only if the posterior view is absurd relative to the prior one” (111). For example, he contends that Newtonian scientists would find the Einsteinian idea that mass varies with velocity unformulatable in their terms. For them, mass is defined as a property of matter that remains constant, and is never gained or lost. This rephrases the revolutionary problem as a linguistic one in which theorists in competing paradigms do not have the necessary vocabulary and linguistic connections to understand each other. Furthermore, Van Fraassen states: “From the posterior point of view, the prior can be made intelligible and the change ratified. From the prior position, however, the posterior view was absurd and the transition to it possible but incapable of justification” (65). Here, we see what Van Fraassen feels is an asymmetry in scientific revolution. The post-revolutionary scientists can examine the revolution and see that it was, in fact, justified by their rationality. For the pre-revolutionary scientists, however, the idea of revolution is unintelligible and absurd.

The above analysis helps to better explain the problem of rationality in scientific revolution and to suggest at least one possible solution. In Lecture 4, Van Fraassen tries to show how incommensurable theory jumps can be rational through the suspension of beliefs and the development of a new linguistic system. In his words: “We can suspend part of what we take for granted, as long as we are willing to rely on a sufficiently large part of our language and prior opinion to describe the suspended part and its possible connections with the world” (139). Here, Van Fraassen argues that it is possible to move rationally from one linguistic system without the

necessity of a prior “blueprint” or specific guidelines for the transition. To do this, we must suspend some opinion and explore its connections with the world using our other linguistic connections. Furthermore, Van Fraassen states that any such transition is made with great fear and that it requires a courageous leap for the person involved. Such would clearly be the case for anyone who is attempting to overhaul the scientific underpinnings of his or her world.

Looking at the example of a Newtonian scientist presented with the idea that mass changes with velocity, Van Fraassen’s claims of linguistic suspension seem correct. In this case, the scientist will try to comprehend the idea that mass changes with velocity. To do this, he or she will need to somehow describe this new property using the vocabulary of the old theory. While this may seem impossible at first, the incorporation of new terms from relativity will allow the scientist to make headway and eventually gain an understanding of a new conception of mass. During the process, the scientist will have a full spectrum of mathematical and scientific knowledge to assist in the transition. By relying on prior opinion and language, the scientist is able to gain the new linguistic connections necessary to understand the scientific revolution as a rational shift; he becomes part of the a posteriori viewpoint. Before the conversion, however, the scientist was not able to comprehend the new theory. This conversion relies heavily on the rational evaluation of new concepts as they are incorporated into the scientist’s language. Clearly, the scientist can undergo this process in a systematic manner rather than relying solely on chance.

Using the previous analysis, Van Fraassen successfully describes a possible mechanism for rational theory choice during scientific revolution. However, these claims seem to contradict his arguments in Lecture 3 describing the emotional aspects of scientific revolution. In this lecture, Van Fraassen brings in Sartre’s account of emotions to describe the necessary transition

between theories during scientific revolution. Van Fraassen believes that scientific revolutions occur when there is a sufficient buildup of empirical evidence against the current theory. After there has been a considerable buildup of counter-evidence “only a leap of some sort (a leap of faith, a ‘throwing away of the prior,’ as the Bayesians say) will provide escape” (92). He sees this leap as a necessary quality of revolution because it allows scientists to re-associate their concepts as described above. Faithful to his empiricist mindset, he uses empirical evidence as the main provider of this revolutionary buildup. Thus, he contends that the true cause of scientific revolution lies in the experiences of the scientist, and he puts little weight on other justificatory factors (i.e. the development of a more aesthetically pleasing theory). For Van Fraassen, this re-association requires such a great disturbance of fundamental concepts that the scientist must engage in it only with “great fear and trembling.” The change in worldview necessary in a scientific revolution must delve into the fundamental workings of the human mindset, thus requiring an emotional mechanism.

Seeking to further determine the form of this leap, Van Fraassen brings in Sartre’s view of emotions. According to Van Fraassen, Sartre’s account takes “the plausible form of characterizing emotion as effecting a substitution of the bearable for the unbearable” (103). For instance, a person experiences an emotional breakdown after circumstances have conspired to the point where a drastic alteration of his or her mindset is the only option. Van Fraassen gives several examples in which emotion is used as a form of escapism. For instance, a woman confessing to her therapist breaks down and cries, a man ordered to do a task that puts him in danger weakens and becomes short of breath, and someone who is treated with condescension by a bureaucrat stops filling out forms and resorts to a fit of anger (103). In each of these situations,

Van Fraassen feels that the actor replaces a frightening or unsettling task with some form of setback behavior to escape the situation.

Van Fraassen draws the parallel between emotional breakdown and scientific revolution by stating that revolutionary science involves the same type of escapism. He states: “The [emotional] conversion itself changes from something unintelligible to something that is certainly intelligible and allows for a rational posterior evaluation on its merits” (108). For Van Fraassen, the experience of the Newtonian physicist attempting to understand mass changing with velocity is similar to the one experienced by the woman who breaks down during therapy. The physicist faces increasing empirical evidence against his theoretical framework and increasing pressure from the scientific community to change his view. Eventually the scientist breaks down emotionally, throws off his prior language, and begins the process of learning the new theoretical framework necessary for the understanding of the new scientific paradigm. The mechanism for the transition is the buildup of diminishing returns and empirical contradictions in the previous theory forcing eventual emotional escapism. This is Van Fraassen’s story of scientific revolution.

While Van Fraassen’s view of scientific revolution is a compelling one, I object to it on two main grounds. First, his attempt to incorporate emotion into an otherwise rational framework forces him into a contradictory set of theoretical assertions. The scientist who must emotionally throw off the bounds of his prior language cannot act in a rational manner. A scientist who flies into an angry tirade in the face of increasing empirical evidence is acting on his basest instincts and in an entirely irrational manner. Indeed, Van Fraassen’s view of emotion is necessarily irrational because of the amount weight he gives it in the revolutionary transition. Without an irrational leap, Van Fraassen’s account cannot explain the scientist’s jump between

the prior theory and the new one. Later in this paper, I will propose an alternate mechanism for scientific revolution that avoids the use of irrational emotions in an otherwise rational framework.

My second objection regards Van Fraassen's failure to address the inherently community-based qualities of scientific revolution. His individualistic, emotional conversion does not scale well to a large conversion of the scientific community. Indeed, Van Fraassen mentions this problem offhandedly at the end of Lecture 3: "There are certainly enough directions as yet unexplored...the ramifications of how a social or communal epistemic enterprise can differ from that of an individual located in a community" (109), but he does not give it any further attention. All his examples of emotional conversions are of a purely individualistic nature, and he does not give any attention to the emotions necessary for a full conversion of a scientific community. Likely, if one scientist underwent such an emotional conversion, the other members of the community would provide a corrective force to move the wayward scientist back to the path of the old theory. For a full revolution to occur, Van Fraassen's model requires something akin to a mass panic, and this occurrence seems impossible in a community acting on the basis of the scientific process.

Looking deeper at the problem of community in scientific revolution, it proves to further invalidate Van Fraassen's focus on individual emotion as the revolutionary mechanism. During a scientific revolution, there will undoubtedly be opposing schools for the old and new paradigms. The new school will contain some followers who have been raised exclusively on the new paradigm, and the old school will contain some followers who will refuse to believe in the new paradigm even to the day of their death. Indeed, it is possible to construct a revolution based entirely on the replacement of the old generation by the teachings of the new generation, but this picture is unsatisfying because it fails to explain the scientists who come to believe in the

new paradigm over the old. If we take on Van Fraassen's view, these scientists become subject to something akin to epistemic torture by the followers of the new school. The new school must bombard the followers of the old with evidence until they finally undergo an emotional breakdown and accept the new theory. In the same way that dictators are able to torture their rivals into submission, the followers of the new paradigm are able to repress the followers of the old through a form of epistemic mind control. Clearly, this process cannot be rational.

To further address these two objections, I will next bring in some analysis from Larry Laudan and Ernan McMullin in attempt to reconstruct Van Fraassen's emotional scientific revolution while maintaining it as a rational restructuring of the scientist's language. In "Dissecting the Holist Picture of Scientific Change," Laudan reexamines the notion of scientific revolution by dividing scientific theories into three parts: ontology, methodology, and values. He argues that each part of a theory can change independently of the others, and he claims that large-scale scientific revolutions occur when the parts change in succession. He introduces this problem as part of a discussion of consensus among the scientific community. He states: "we solve the problem of consensus once we realize that the various components of a world view are individually negotiable and individually replaceable in a piecemeal fashion" (144). For Laudan, scientific revolution consists of a rational stream of events that slowly replaces each part of the theoretical worldview. In this way, scientists can rationally argue for their respective worldviews and eventually come to consensus about the solution.

According to Laudan, when scientific revolution is examined from a broad perspective the conversion seems to be irrational, but when looking more closely it becomes clear that each step in the process is a rational move. In his words: "The point...is that a sequence of belief changes which, described at the microlevel, appears to be a perfectly reasonable and rational

sequence of events may appear, when represented in broad brushstrokes...as a fundamental and unintelligible change of world view” (138). Unlike Van Fraassen’s violent, emotional revolutionary picture, Laudan describes scientific revolution as a more gradual process of rationally replacing old theoretical ideas with new ones in a piecemeal fashion.

To further justify his theory of scientific revolution, Laudan describes what revolutionary change on the microlevel might look like. He gives the following scenario: “If a scientist’s methodology fails to justify his ontology; if his methodology fails to promote his cognitive aims; if his cognitive aims prove to be utopian – in all these cases the scientist will have compelling reasons for replacing one component of his world view” (145). Here, Laudan points out that there are many scientific conundrums that do not warrant the wholesale replacement of a theoretical model. For instance, if a scientist finds that his scientific practices can no longer justify the theoretical models that he holds, he will be forced to change his scientific practices. This is precisely what occurred with the rise of quantum mechanics in the twentieth century. Scientists were forced to abandon the previous notion of deterministic cause and effect and take up a more probabilistic approach to describing particles. The development of new experimental approaches allowed for the justification of probabilistic laws, such as the prediction of spin-up and spin-down electrons in the Einstein-Podolsky-Rosen experiment.<sup>2</sup> Up until this time, scientists performed experiments and developed theories to predict outcomes, and probability was seen as an indication of ignorance. For any probabilistic theory, scientists believed that there was a better theory that did not involve probability. After this experiment, it was sufficient for scientists to probabilistically predict quantum mechanical outcomes. This change in

---

<sup>2</sup> In this experiment, the researchers performed a simple quantum mechanical reaction that resulted in two electrons. According to the laws of quantum mechanics, the electrons must have opposite spins. The researchers found that quantum mechanics could not predict which electron would be spin-up and which would be spin-down. It could only determine the probability of each result: clearly one-half in this case. See (Kosso 137) for more details.

methodology, however, did not result in a full shift of the scientific community to quantum mechanics. The wholesale acceptance of the theories would only come after more experimentation and scientific formulation.

One possible objection to Laudan's view of scientific revolution over Van Fraassen's is that it cannot deal with truly deep revolutions. The terms of shallow and deep revolutions were outlined by Ernan McMullin in "Rationality and Paradigm Change in Science." In this paper, McMullin describes shallow revolutions as follows: "These changes involved the formulation of a new and more comprehensive theory. But they left more or less unchanged the epistemic principles governing the paradigm itself" (123). Shallow revolutions are those that change the theoretical backgrounds of science, but they do not affect what is considered a good theory. On the other hand, in deep revolutions:

"In these cases, adoption of the new paradigm carries with it adoption of a somewhat different rationality at the metalevel. The advantages of the new theory are so marked, in terms of a minimal level of shared values, that a shift in the values themselves is ultimately taken to be warranted." (127).

In McMullin's deep revolutions, the very values that shape theory selection are affected. For example, the quantum mechanical revolution overthrew the idea that scientific theories are better if they more precisely predict the outcomes of events. After this revolution, scientists accepted that the quantum world is inherently probabilistic, and they no longer saw probability as a shortcoming in theories. On the other hand, the Einsteinian revolution was a shallow revolution because both relativity and Newtonian physics are weighed using the same set of values.

At first, deep revolutions seem to pose a problem for Laudan's piecemeal scientific revolution because it is difficult to imagine how a scientist could rationally change the very

values upon which his rationality is founded. It is here that Van Fraassen's idea of linguistic restructuring can help to better understand the process of deep revolution. During a deep revolution, the scientist is faced with an irreconcilable problem. She has rationally changed her ontological claims and scientific methodology to the point where they are incompatible with her values of what makes a good theory. To make the final jump to the new paradigm, the scientist must abolish the very language of rationality upon which her science is built. She is able to do this because she has already learned the language of the new theory during the replacement of her ontology and methodology in the previous steps. There is only one possible way to regain consistency in her theory set, and that is to rebuild scientific rationality on a new set of values. Prior to the replacement of the scientist's ontology and methodology, she could not even comprehend this move, but somewhere during the process this move became a rational alternative. In this account of scientific revolution, there is no place for emotion as a driving mechanism of theory selection. Thus, Van Fraassen's irrationality is not introduced into the picture. While emotions may occur in the process, as they should in any scientist who takes his or her profession seriously, they are not involved in theory selection. The theory selection process is fully rational.

Furthermore, this new view of scientific revolution helps to better address the problem of community and consensus in theory selection. If theory choice is held to be rational and piecemeal in nature, the scientific community can easily come to consensus through discussion and research. There is no torturous buildup of empirical evidence against the followers of the old paradigm, and there is no final emotional release and breakdown. Instead, the followers of the old paradigm begin to adopt the ontology and methodology of the new paradigm by learning a new language. After incorporating this language into their belief set, they finally switch over

into a new value system and become followers of the new paradigm. Those who have not yet made this shift either eventually come to their rational senses or pass away still trying to grasp the new language of science. After this transitional period, the most rational theory has won.

In conclusion, Van Fraassen's linguistic restructuring along with Larry Laudan's piecemeal account of theory change combine to provide a new view of scientific revolution. By describing revolutionary practice without emotional mechanisms, this view avoids many of the shortcomings of Van Fraassen's account of scientific revolution. More specifically, it better preserves the rationality of theory selection and allows for rational consensus among the scientific community. Furthermore, this view provides accounts of both shallow and deep revolutions by allowing the piecemeal change of ontology, methodology, and values depending on the circumstances. Ultimately, the preservation of rationality in scientific revolution saves scientific advance from being dumb luck or emotional irrationality. Additionally, this account of scientific revolution allows us to define a spectrum of scientific revolutions. Revolutions that occur quickly and result in changes in several of the above categories can be classified as more revolutionary than slower and less influential revolutions. This avoids the difficulty of setting a line between normal science and revolutionary science. The next step is to examine the implications of rational theory choice on scientific realism and on the relationship between science and reality. While rational theory choice can perhaps make the scientist sleep a little easier, there is no guarantee that a rational scientific method will lead to an accurate picture of the world. After all, as Van Fraassen would surely agree, experience is an imperfect eyeglass.
