## "I'm Here to Make You Feel Better"

"The robot could sense how you're responding," Michaud says. "If it felt pushback, it would abandon the hug."

### Side by Side

Building a robot that can "see" has been one of the stiffest challenges. "A robot that is much shorter than you are will have a hard time tracking and processing your facial expressions," Mataric says. As an alternative, her research team is creating machines that interpret other physiological data, such as skin temperature, heart rate and galvanic skin response, which is a measure of electrical resistance that corresponds to heightened emotions.

The better a robot can "perceive" and respond to human signals, the more likely a person will be to take its direction. In that vein, it's important that responses not be static. "People may be open to direct encouragement when they're fresh and require more empathy when they're tired," says Reid Simmons, a research professor in robotics and computer science at Carnegie Mellon University in Pittsburgh. "So the robot may need to change its speech and expression, just as a good therapist would."

It also helps if the machine's "personality" matches the user's. Working with stroke patients, Mataric has found that those who are extroverted prefer outgoing robots who stand close and speak fast with high-pitched voices and exhort them with such phrases as "You can do more than that, I know it" and "Concentrate on your exercise." Introverts respond well to gentle nudging: "I know it's hard, but it's for your own good" and "Very nice; keep up the good work."

Although most children seem to have an easy time working with robots, adult users are more demanding. Still, the majority eventually embrace having a robotic companion and may even start playing games with it, hiding from it or trying to trick it into thinking they've already completed their exercises.

A robot must also be able to follow certain social conventions, such as getting on an elevator without mowing down other passengers. "Parents teach their children to wait until other people get off an elevator before stepping in," Simmons says. "But that's not the true rule, because if you wait until everyone gets off, you'll stand there forever. The real question is, which people are intending to get off?"

cognitively impaired individuals. Walking side by side with someone is much harder for a robot than following or leading, according to Simmons. "The robot has to keep pace, not bump into the person, and know how to give directions based on the side of the person it's on," he says. "When you're walking with someone and talking, you give nonverbal cues to change direction, such as gesturing or moving slightly ahead."

#### Not Too Human

Beyond determining what socially assistive robots can do, researchers must consider how the machines should look. A phenomenon called the "uncanny valley," a phrase coined in 1970 by Japanese roboticist Masahiro Mori, suggests that the more humanlike the robot, the more humans will relate to it, but only up to a point, at which that good rapport suddenly drops off (the valley). "Machines that are almost, but not quite, like a person are worse than those that are either completely humanlike or a bit further away," Simmons says.

That's particularly true of robots designed to work with children with autism, who want something decidedly machinelike. Kaspar, for example, a diminutive robot being tested with children with autism in the United Kingdom, has a minimally expressive face and wires sticking out of its neck and wrists to make it clear to the kids that they're playing with a robot. "We tested another robot that looked like a doll with eyelashes and color on its lips, and the children didn't like that one as much at first," says Dautenhahn, who headed the team that created Kaspar.

Certainly no one would mistake CosmoBot, a 16-inch-tall robot designed by AnthroTronix, an engineering company in Silver Spring, for a person. And that seems to suit Libby, a 6-year-old with autism, just fine. Before being introduced to CosmoBot, Libby couldn't imitate even the most basic actions. But after several weeks of playing with the robot, she was mirroring its motions as it led her through a Simon-says game of raising her arms, patting her head and clapping.

"Her mother and the professionals who saw this were in tears," says Carole Samango-Sprouse, director of the Neurodevelopmental Diagnostic Center for Young Children at George Washington University. "It was incredibly encouraging that the robot, through repetition and predictable behavior, was successful in getting her to perform the motions she had seen adults doing for years."

Robots can also teach children with special needs how to play with one another. If a child is touching the robot inappropriately (slapping, say, instead of stroking), the robot may back away or emit a warning beep to encourage the child to change his behavior.

Dautenhahn has noticed that children with autism who play with Kaspar may also spontaneously begin interacting with their teachers. "One withdrawn boy who never played with other children or his teacher became very interested in Kaspar's eyes," she says. "He pointed to Kaspar's eyes, then to his own, and then, smiling, to his teacher's eyes. This was an invitation to share, and the boy and his teacher played together."

Children with physical disabilities also respond well to robots. In three schools in Austria, PlayROB gives children with cerebral palsy and other severe disabilities the chance to play independently. Controlling the robot with a joystick, buttons, their mouths or even just head movements, the children can direct it to build Lego structures and do additional activities that let them experience the creative expression, spatial recognition and accomplishment that other children get from playing.

#### What's Next

The technology is ready, but researchers say they need to learn from clinicians which robotic features are needed to treat a disorder. And there remains a gap in funding: money for the research to prove that socially assistive robotics is ready to move out of laboratories and into schools and homes in a wide variety of capacities.

"Right now, funding is available to create robots to support the elderly and the very young, but what happens to people in the middle?" Dautenhahn asks. "Older children who are autistic or in wheelchairs grow up to be adults with those disabilities. I'm waiting for others to identify those needs so we can analyze how robots can help."
