Self-Management Coach

In the context of healthcare, autonomy is a critical component for patients to be able to manage their health conditions. The Self-Management Coach is designed to help patients manage chronic conditions by providing personalized feedback and support. The model consists of several components: a VAD-space model, agraded cueing model, and a nutrition education model. The VAD-space model captures the user's emotional state and context, while the graded cueing model adapts the model's responses based on user feedback. The nutrition education model provides health education through interactive feedback. The interaction between these models allows for dynamic adaptation to user needs, making the Self-Management Coach a powerful tool for promoting self-management in healthcare.

Future Work

Future work includes expanding the model to incorporate multiple goals and domains, validating the model in real-world scenarios, and exploring the impact of autonomy on patient outcomes. Additionally, the model could be extended to other chronic conditions, and the effectiveness of the graded cueing model in other domains should be investigated. Finally, the model's potential to improve patient outcomes should be evaluated in clinical trials.

Autonomy-Encouraging Task Feedback

Imitation Practice for Children with ASDs

The graded cueing model was implemented in a study to understand children's imitation and communication abilities in a real-world setting. The model was validated in a study of imitation feedback with children with autism spectrum disorders interacting with a robot. The model showed promising results, indicating its potential for use in real-world applications. The model's effectiveness in encouraging imitation and communication abilities suggests its potential for use in other domains, such as education and therapy.

Emotion Shaping Feedback

Validation in Emotion Space

The graded cueing model was implemented in a study to understand children's imitation and communication abilities in a real-world setting. The model was validated in a study of imitation feedback with children with autism spectrum disorders interacting with a robot. The model showed promising results, indicating its potential for use in real-world applications. The model's effectiveness in encouraging imitation and communication abilities suggests its potential for use in other domains, such as education and therapy.

Reducing Anxiety in Hospitalized Children

Child life services are the members of pediatric hospital staff that discuss medical procedures with children to prepare them emotionally for an upcoming intervention. In this study, we will use an empathetic child-robot interaction to reduce children's anxiety about receiving an IV insertion. Specifically, we will train the robot to engage in a conversational interaction with children, providing information and support. The robot will be autonomous, allowing it to adapt to the individual needs of each child. The study will be conducted in a hospital setting, with children receiving an IV insertion.

Model Integration

The next step in the development of the Self-Management Coach is to integrate emotion shaping feedback, which will allow the model to adapt to user needs in real-time. The integration of emotion shaping feedback will enable the model to provide personalized feedback and support, making it a more effective tool for promoting self-management in healthcare. The integration of emotion shaping feedback will also allow the model to adapt to user needs in real-time, making it a more effective tool for promoting self-management in healthcare.

Model Development

Self-Management Coach

The next step is the development of the Self-Management Coach to incorporate emotion shaping feedback. The model will be validated in a study of imitation feedback with children with autism spectrum disorders interacting with a robot. The model will be autonomous, allowing it to adapt to the individual needs of each child. The study will be conducted in a hospital setting, with children receiving an IV insertion.
